

Board games recommender

Matěj Bukáček, Petr Janík, Jakub Kraus, Michal Salášek,
2023

Goal & Motivation

- Develop a recommender system for board games
 - users who like to play board games and want to try new ones
- Possible monetization:
 - e-shop
 - referral links to e-shops

Data

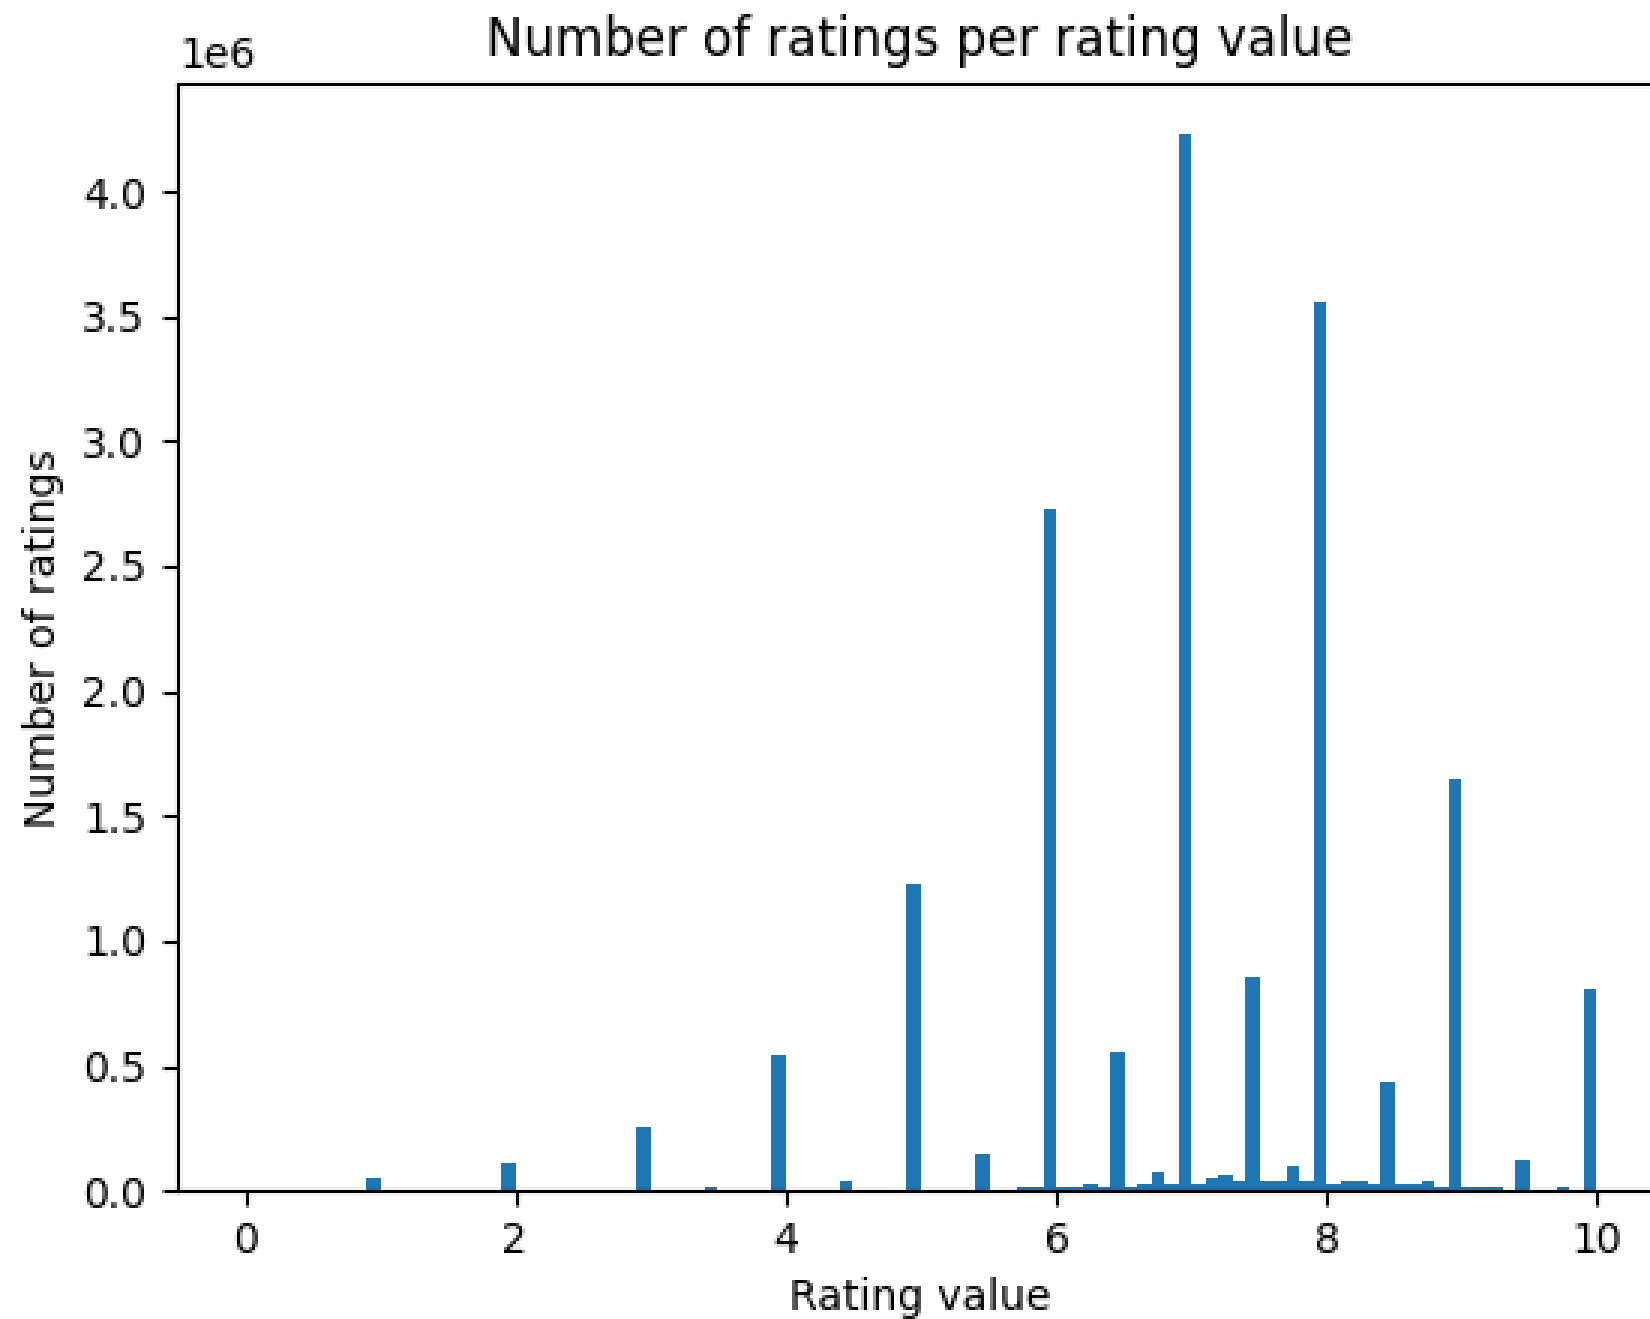

- from [kaggle](#)
- games , mechanics , subcategories , themes
- user_ratings
 - BGGId - BoardGameGeek game ID
 - Rating - Raw rating given by user
 - Username - User giving rating

Data preprocessing

- removed duplicate ratings
- removed users with less than 10 ratings
- removed games with less than 10 ratings

Data analysis

- **18 340 284** user ratings
- **224 557** users, **21 919** games, **157** mechanics, **217** themes, **10** subcategories
- density of user ratings matrix: **0.37%**
- ratings per user:
 - average: **81.67**
 - median: **39**
 - maximum: **6478**
- average rating: **7.10** (range **[0, 10]**)

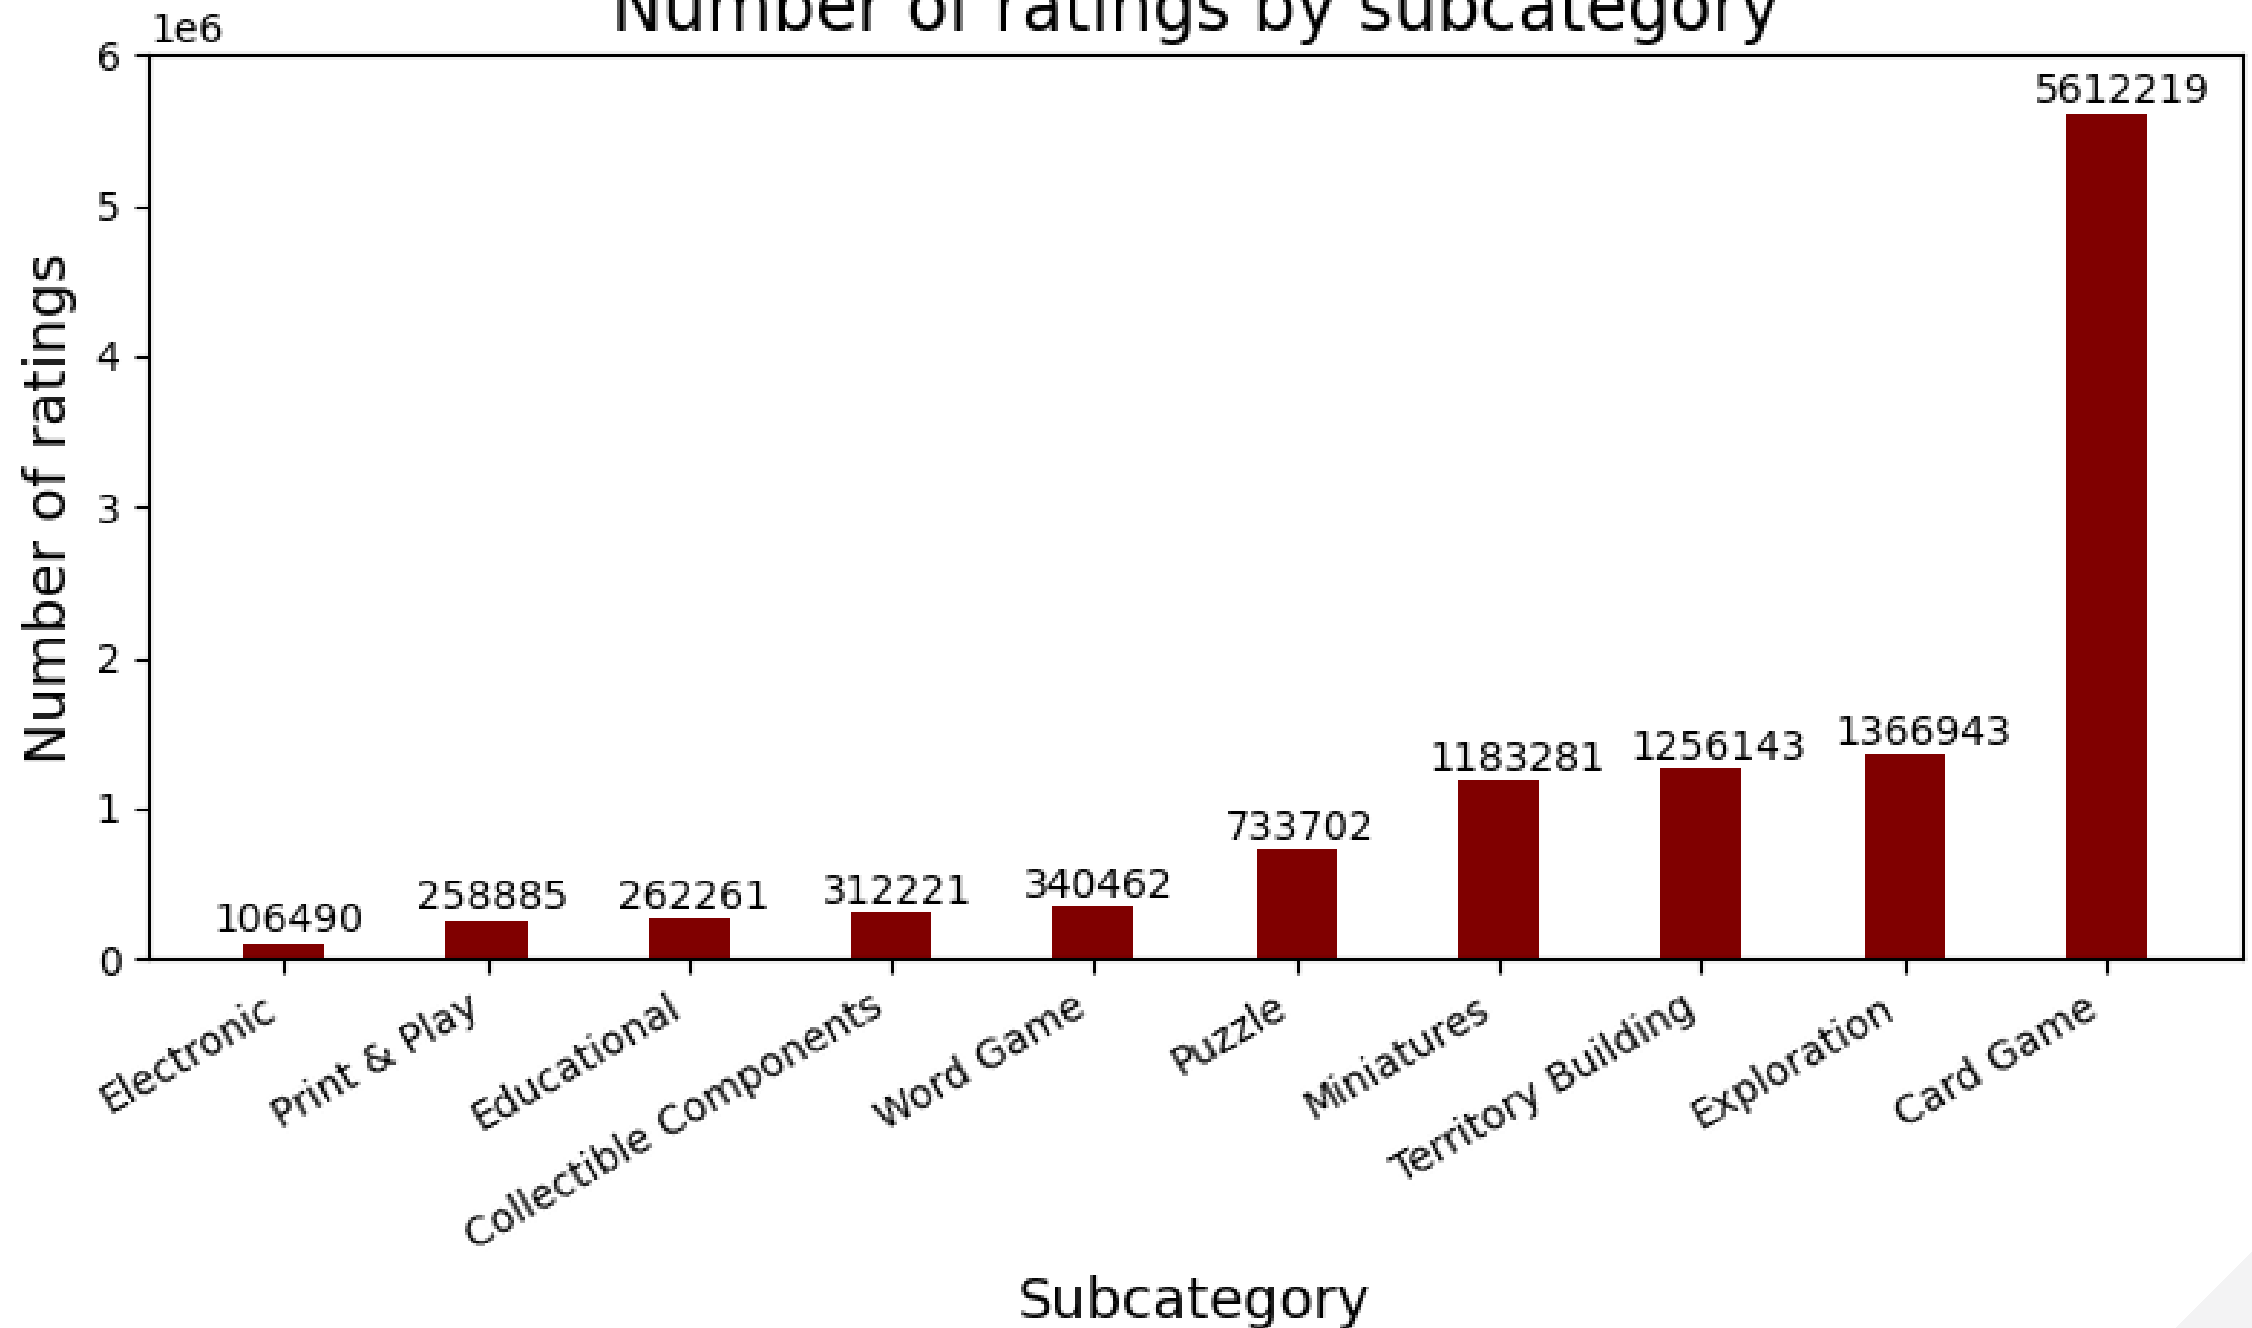

Number of users per number of ratings

Average rating of games by subcategory

Number of ratings by subcategory

TF-IDF

- most of relevant data are binary flags + some numerical values and Description
- pipeline:
 - convert binary flags and numerical values to text
 - concatenate with description
 - compute TF-IDF matrix
 - compute cosine similarities
 - choose rows with rated games
 - sort games based on similarity score

Problems

- during development:
 - converting everything to text (so that library function could be used)
 - mapping index in matrix to index in database
- finished product:
 - reimplementations

Evaluation

- no exact metric, just by feedback
- mostly positive feedback, but problems when game has too many reimplementations
(those are very similar, so they get high score)

Latent factors

- **idea:**
 - we are trying to model "taste" of users and "features" of items
 - matrices of user / item latent factors
- **approach:** minimize squared errors (+ regularization)
- **method:** stochastic / mini-batch gradient descent

$$\hat{r}_{ui} = q_i^T p_u$$

$$\min_{q,p} \sum_{(u,i) \in T} (r_{ui} - q_i^T p_u)^2 + \lambda(||q_i||^2 + ||p_u||^2)$$

Pipeline I

- split dataset into **train**, **validation** and **test** set
 - **idea**: all games should be present in all three datasets

X_train_BGGId_top_50

X_val_BGGId_top_50

Pipeline II

- use training set (user ratings) to **train** the model
 - adjust matrices of user / item factors using **gradient descent**
- use validation set to prevent overfitting
 - compute **RMSE**
 - apply early stopping if necessary
- use test set to **evaluate** the trained model (RMSE)

Initial results I

- **stochastic** gradient descent too **slow**
 - necessary to reduce data
- adopt **mini-batch** gradient descent
 - allows to train on full data with more epochs / hyper-parameter tuning

Initial results II

- predictions not quite "reasonable" (no obvious pattern)
 - 2 latent factors \rightarrow 2D plane (similar to PCA) \rightarrow **find features** in similar / "opposite" clusters
 - compare RMSE of latent factors model with **baselines**

RMSE comparison

- global mean: 1.530
- user mean: 1.376
- item mean: 1.316
- global mean + item/user bias: 1.230
- latent factors: 1.19
- latent factors with global effects: 1.19

New user

- approximate **user factors** from ratings
- item factors matrix is constant
- least squares
- simple approach (systems of equations)

Experience report

- necessary to implement gradient descent myself
- necessary to make mini-batch
- additional effort to confirm algorithms are implemented correctly
- computing recommendations for new user initially unclear

Memory based CF

- **pipeline:**
 - ratings matrix (users \times games) - get users that rated the same games as me
 - unrated game - keep users who rated it
 - find k most similar users to me
 - get mean rating

Qualitative evaluation

- only on local device (not integrated into the app)
- low amount of feedback - testing in Postman
- not very intuitive, much novelty and unexpected recommendations
- stick to category - RPGs recommend RPGs

```

Encountered problems

- performance - not usable in real-time, not deployed
- implementation - several new technologies (also programming on Windows)
- memory - creation of ratings matrix on local device
